That is, the functions  $\psi_{j,k} = 2^{k/2}\psi(2^k \cdot - j)$ ,  $j, k \in \mathbb{Z}$ , form a complete orthonormal system for  $L^2(\mathbb{R})$ . In this work, we shall call such a function an orthogonal wavelet, since there are many generalizations of wavelets that drop the requirement of orthogonality.

All of these guys are orthogonal. Let me write that down. All of the vectors are orthogonal to each other. And of course they're not orthogonal to themselves because they all have length 1. So if you take the dot product with itself, you get 1. If you take a dot product with some other guy in your set you're going to get 0.

In mathematics, orthogonal functions belong to a function space which is a vector space that has a bilinear form. When the function space has an interval as the domain, the bilinear form may be the integral of the product of functions over the interval:  $\langle f, g \rangle = \int_a^b f(x)g(x)dx$ . The functions  $f$  and  $g$  are orthogonal when this integral is zero, i.e.  $\langle f, g \rangle = 0$  whenever  $f \neq g$ .

The cylindrical system is used for problems involving cylindrical symmetry It is composed of: (1) the radial distance  $r$ , (2) the azimuthal angle,  $\theta$ , and  $z$ , which can be thought of as height As in the case of the Cartesian system,  $r$ ,  $\theta$ , and  $z$  are mutually perpendicular or orthogonal to each other, e.g.,  $r \perp \theta$ , etc.
